#### EXECUTIVE SUMMARY

Several pilot GRS-IBS projects have been constructed in Oklahoma over the past years (i.e. since 2014) following the FHWA's multi-year EDC initiatives, and efforts made by the ODOT Local Government division, the BIA Office in Anadarko, OK, and several counties in Oklahoma. The PI's research team has also completed ODOT-sponsored, full-scale laboratory and field studies in which GRS abutments have shown satisfactory structural performance. Meanwhile, a set of 34 GRS-IBS projects are scheduled for construction in Grant County in the near future, which is a significant advancement in the use of GRS-IBS to replace structurally deficient and functionally obsolete bridges in Oklahoma.

In this study, comparisons have been made between the cost of GRS vs. conventional bridge abutments to provide some insight into possible cost advantages that the newer GRS abutments could have in future like projects in Oklahoma. Different offices and individuals were contacted to obtain information on construction costs, and possibly, construction speed of the GRS and select conventional bridges. However, collection of cost information on both the GRS and conventional bridge alternatives proved to be significantly more challenging than had been anticipated for a variety of reasons that are discussed in this report. Additionally, except for the bridges in Kay County, no construction speed information was available on any other bridges for comparison purposes.

The cost information that was possible to collect and compile has been analyzed and presented separately for different counties where GRS abutments have been built as pilot projects. Additionally, the cost data on each bridge was itemized separately relative to its abutments and its superstructure in order to provide a reliable comparison between different choices of abutment, if both alternatives (i.e. deep foundation vs. GRS) would be equally feasible for a given project.

iv

The latest elevation surveys of bridges in Caddo County (i.e. the GRS bridges that were built most recently) had been obtained through Mr. Scott Garland, PE. Additionally, Mr. Bryan Cooper had supplied our team with the latest photographs that showed the conditions of different GRS bridges across the state. The above information indicated that all GRS bridges have been performing well with no report of any structural problems to date.

Results of this study show that construction costs of the few GRS bridges that have been constructed in Oklahoma, have been overall either comparable to, or less than those of conventional bridges of comparable size. Additionally, bundling of projects and increased experience with GRS abutment construction by contractors and local forces throughout the state could improve their cost advantages over conventional alternatives. Among major advantages of GRS abutments over conventional alternatives are that they can help eliminate the bump-at-the-end-of-the-bridge problem, and their construction requires equipment that is commonly available to many contractors and local forces. Therefore, more widespread familiarity with their construction technique can lead to a larger pool of potential contractors and local forces for their construction, resulting in lower costs, especially for smaller bridge abutments.

During the course of this study, it was observed that there is a paucity of welldocumented, cost and construction speed information on both the GRS and conventional bridges on local roads in different counties. Developing a centralized system to record and maintain such data would provide a valuable reference database for different stakeholders, which can help ensure more cost-effective bridge projects across the state in the future. This is an area that this research team can help with, and would be worth considering in the continuation of this study.

#### 1. INTRODUCTION

In this study, cost data and other related information (size, location, etc.) on the existing and ongoing GRS-IBS projects were gathered and compiled in order to compare against those on select conventional bridges in Oklahoma as much as it was found available from different parties, as explained in this report.

Different offices and individuals were contacted for information on GRS- and conventional-abutment bridges relative to their cost and construction speed, per the objective of the study. This included ODOT Local Government, Bridge and Construction Divisions, the BIA, contractors, County Commissioners, and engineers at several Field District Offices (i.e. those in Districts 1, 3, 4 and 7, corresponding to the existing GRS bridge locations). However, obtaining such information turned out to be much more challenging than we had anticipated due to various reasons. For instance, the information had not been necessarily recorded and archived completely, or kept in one central place for future access. There have been changes in personnel and in office locations, and even occurrences of office damage, which made access to such data even more challenging. Some county commissioners who were closely involved with the construction of GRS bridges in their counties were no longer in office. Even some GRS bridge contractors were no longer in business. Pandemic-related challenges had also exacerbated the situation and made access to any construction records more complicated.

It was ultimately possible to gather cost data on most of the GRS bridges and a few conventional bridges for comparison purposes, as presented in this report. However, little information could be found on their construction speed that could lead to any meaningful comparisons between these alternative construction techniques. Evidently, this is because these local bridges are either built e.g., using county forces for whom

1

logging the details of a bridge construction time/speed may not serve any particular purpose, or by contractors who may be involved with several construction projects at a time, and therefore, recording the construction time of any particular local bridge at hand would not be practical or purposeful either.

As a starting point, we reached out to Mr. Walt Peters, PE at the ODOT Bridge Division and received a list of conventional bridges that included information such as their location (county and geographical coordinates), identifying numbers and construction year, among others. **Figure 1** shows a snapshot of such information in tabulated form. In communications with Mr. Bryan Cooper (LTAP Manager), we received the geographical coordinates of the existing GRS bridges in Oklahoma in addition to snapshots of their existing conditions, which indicated that they were all in good operating conditions. Mr. Tom Simpson, PE (BIA) was instrumental in providing construction cost data on several GRS and conventional bridges in Caddo, Kay and Lincoln Counties.

**Figure 2** shows a map indicating the locations of existing GRS bridges in Oklahoma (in orange) and possible conventional bridges that we had originally identified for comparison purposes (in blue). **Table 1** shows the locations of existing GRS-IBS projects in Oklahoma based on the information provided by Mr. Tom Simpson and Mr. Bryan Cooper. Cost-related data that were sought and collected on GRS and conventional bridges in different counties are described separately in the following sections. The only exceptions are the single GRS bridges in Haskell and Ottawa counties for which cost information was not available during the period of this project. On the other hand, a significant amount of information was obtained on the upcoming GRS bridges in Grant County, which is discussed in a separate section as well. In this report, the terms GRS-IBS, GRS-abutment bridges and GRS bridges are used interchangeably.

Table 1. Inventory of GRS-abutment bridges in Oklahoma

**Figure 3** shows histograms of abutment height and width for the GRS-abutment bridges built, or planned for construction, in different Oklahoma counties to date. Data in these figures show that the vast majority of the bridge abutment heights (i.e. 75%) is within the 7-14 ft range. Germane to their width, all existing GRA abutments in Kay and Caddo counties are 30'-wide or narrower, whereas the upcoming Grant County bridges are all designed with 30±2 ft-wide abutments.

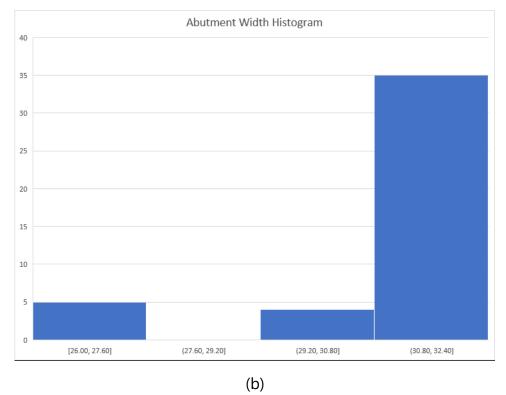

Figure 3. Histograms of GRS Bridges in Oklahoma relative to: (a) abutment height in ft. (b) bridge width in ft. (vertical axis: number of occurrences)

#### 2. CADDO COUNTY

Despite several challenges that were mentioned in the previous section, Caddo County offices (Districts 2 and 3) courteously made attempts to search for construction information on GRS and comparable conventional bridges. The staff at the District 2 office were able to find documents on two GRS bridges that were analyzed as shown in **Fig. 4**, which indicates that bid prices from different contractors can vary significantly. An important factor could be the familiarity of the contractor with the GRS-IBS construction guidelines and requirements. In the particular example shown in **Fig. 4**, Contractor A had built several GRS bridges in different counties in Oklahoma, which seems to have helped this contractor submit significantly lower bids for the two GRS-IBS projects in Caddo County. The importance of familiarity with the GRS construction practice is also discussed later in this report on field-scale model construction and testing at OU. Additional related discussion can also be found in a recent FHWA publication (Nicks 2019).

**Fig. 5** shows example list of candidate conventional bridges in different counties (in this case, Caddo County) that were communicated to different offices to obtain construction cost information and compare with the corresponding data on GRS bridges. A map showing the locations of these bridges is given in **Fig. 6**. We ultimately were able to receive cost data on only two conventional bridges in Caddo County from Mr. Tom Simpson that could be used for direct comparison of abutment alternatives. The data on a couple of other conventional bridges were available in the form of total costs only (as opposed to separately on abutments). Cost information on two other conventional bridges in Kay County was also available, which was used for a broader comparison of the abutment types relative to their costs. The costs of the two conventional bridges in Kay County were practically the same and equal to \$60,000 (see **Section 4**).

**Figure 7** shows cost comparisons between GRS bridges in Caddo County and the said conventional bridges. The cost data are plotted both as a function of the abutment height and facing area, which has also been used as a parameter in cost comparison studies (e.g. Nicks 2019). Data in **Fig. 7** indicate that GRS bridge costs are somewhat higher (i.e. up to 11%) than those of conventional bridges of the same height or facing area for the cases examined. This could be attributed to the fact that the GRS-IBS is a newer construction technology and as a result, contractors and county forces are not as

familiar with them as they are with conventional bridges, which in comparison, have been built routinely across the state for several decades.

### 3. GRANT COUNTY

In 2019, ODOT was awarded a total of \$3.47 million to help replace 34 bridges in Grant County through the Competitive Highway Bridge Program (CHBP). The project requirements included innovative technology, financing, and project delivery aspects (Williams 2019). The innovative technology aspect of the project included precast concrete beams that included prestressed elements. Innovative financing included securing funding from different stakeholders as shown in **Table 2**. Innovative project delivery included a unified set of plans and standardized designs for a bundle of 34 bridges, which helped reduce the workload and make the entire project cost effective through the economy of scale. It also involved a streamlined environmental study and approval process (**Table 3**; Williams 2019).

Table 2. Different sources of funding for the upcoming GRS bridges in Grant County(Williams 2019)

CIRB/STP	County	ODOT	CHBP Grant
\$2,751,000	\$720,000	\$2,038,800	\$3,468,000

Survey	March 2020
Hydraulics	May 2020

PS&E	May 2021
Federal Authorization - Bid Letting	August 2021

 Table 3.
 Timeline of GRS bridges in Grant County (Williams 2019)

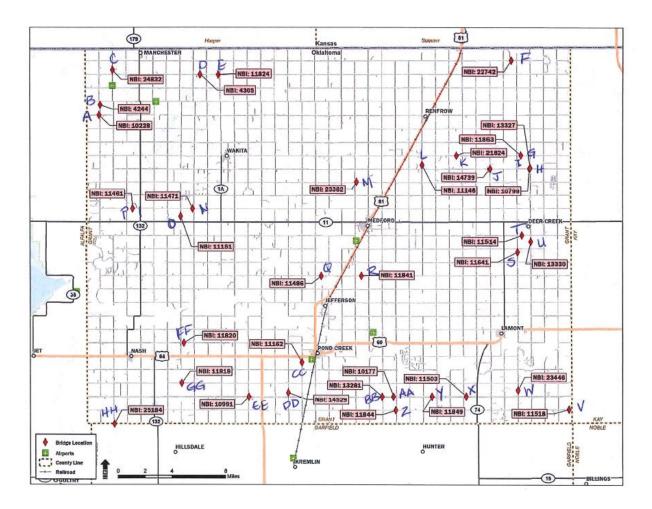

Figure 8. Location map of bridges in Grant County that will be replaced with GRS-IBS (from Ms. Shelly Williams, PE)

The GRS-abutment bridges in Grant County are expected to reduce the structurally deficient bridges in the county by 20%, boost the local economy, and improve traffic safety for the local communities (Williams 2019). A map of different GRS bridge locations across the county is shown in **Fig. 8**, and example bridges that are slated for replacement with GRS-IBS are shown in **Fig. 9**.

**Figure 10** shows cost estimates for bundled GRS-IBS projects in Grant County as provided by Ms. Shelly Williams, PE. Data in **Fig. 10** indicate that the estimated cost of these GRS abutments, regardless of their bridge span, is ~\$71K, which is significantly

lower than the bid amounts in **Fig. 4**. Comparison of data in **Figs. 4 and 9** indicates that bundling of GRS-IBS construction, as has been adopted by ODOT for Grant County projects, could indeed lead to significant cost savings relative to the occasional and case-based construction of these bridges.

Figure 9. Example bridges/crossings in Grant County that will be replaced with GRS-IBS

Meanwhile, the large number of GRS projects that are planned in Grant County provides an opportunity to explore the possible benefit of developing correlations between select attributes of GRS bridges (e.g. bridge span or plan area, abutment height, etc.) and the anticipated construction costs in a future study. For instance, **Fig. 11** shows a comparison between estimated costs based on actual contractor's bid amounts on one of the GRS bridges in Caddo County, and estimated amounts (90% AWP) directly reported for one of the GRS bridges in Grant County (labeled as A-A in **Fig. 8**). The bid amounts on the Caddo County GRS bridge were prorated based on the difference between the sizes of plan areas of the two bridges.

Figure 10. Cost estimates for bundled GRS-IBS projects in Grant County (Courtesy of Ms. Shelly Williams, PE)

Results in **Fig. 11** show a good agreement between the two estimated amounts relative to the overall abutment cost (i.e. \$69,028.00 vs. \$70,385.00). They also indicate that the estimated total cost of \$183,263.60 (i.e. prorated cost of the Caddo County bridge) is within the ballpark of the two estimates directly obtained on the Grant County bridge (i.e. \$167,734.00 and \$204,095.25) after cost adjustments were made for the actual type of the superstructure used (e.g. steel vs. prestressed concrete beams).

Figure 11. Comparison between estimated costs of Bridge A-A in Grant County using different sources

It is understood that the accuracy of such estimates can depend on a wide range of variables including abutment height, bridge span, site conditions, bundled vs. unbundled estimates (i.e. economy of scale) and construction-related factors. However, correlations developed using larger databases could serve as a preliminary costestimate and decision-making tool for interested parties in similar projects in the future. For instance, if both a conventional and a GRS-abutment bridge alternative are determined to be equally feasible for a given site, these correlation-based cost estimates could shed some light on possible cost-differences that would be anticipated between the two systems. **Table 4** shows a summary comparison of selected GRS and conventional bridges in several other states based on various sources. Results show that cost-savings between 16%-63% have indeed been achieved.

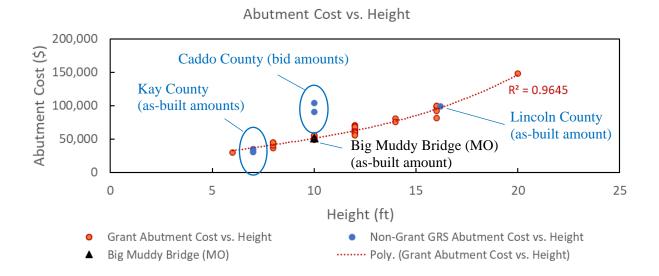

The '90% AWP estimate' cost data on GRS bridges from Ms. Melissa Davis (Grant County project manager) was further analyzed as shown in **Fig. 12**, which indicates an interesting trend with the abutment height and facing. Results in **Fig. 12** show that:

- 1. Estimated abutment costs for Grant County bridges indicate a clear and consistent dependence on abutment height. They also show a very good agreement with the actual costs of GRS bridges of comparable height in Lincoln County (1 bridge) and Kay County (4 bridges). The design widths of Grant County bridges varied within a fairly narrow range of 30±2 ft and therefore, bridge width was considered a distant secondary variable in this analysis. Another cost datapoint from a GRS bridge project in Missouri is also provided for comparison purposes (LCBH Solutions 2018), which shows very good agreement with other datapoints.
- 2. For abutment heights of up to 12 ft, abutment cost effectively increases linearly (i.e. proportionally) with height. However, the cost starts to increase at a higher rate for taller abutments. This observation confirms our expectation that the cost-effectiveness of GRS abutments relative to conventional abutments could diminish in the case of taller abutments. The use of large-block-facing abutments could help speed up abutment construction to some extent, leading to some cost savings in such cases (Hatami *et al.* 2020, Redi-Rock 2020 Fig. 13). However, it would require local availability of approved large blocks and experienced contractors, and

15

therefore, confirmation of such savings awaits additional large-bock abutment construction projects in the future.

Abutment Cost vs. Facing Area

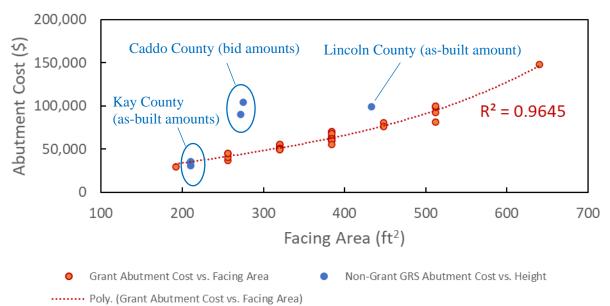

Figure 12. Cost estimates for Grant County GRS bridges (abutment cost only) as compared to the cost data available on GRS bridges in other counties as a function of (a) abutment height, (b) abutment facing

Furthermore, the sheer volume of tall GRS abutments requiring significant amounts of select aggregate, reinforcement material and labor could erode their otherwise, demonstrated cost advantages to some extent for very tall bridge abutments. 3. Results in Fig. 12 could be considered as preliminary guidance to estimate the possible cost of GRS abutments in an Oklahoma county relative to comparable conventional abutments. However, further improvement in the accuracy and reliability of the results in Fig. 12 awaits additional cost data on similar projects in the future.

Furthermore, the accuracy of cost estimates can highly depend on several other factors such as: site conditions and scale of excavations necessary for the abutments, any stream or traffic rerouting provisions required, source and availability of materials (i.e. fill aggregate, reinforcement and blocks), construction of the bridge by local force vs. contractors, and familiarity of the construction crew with GRS abutment construction techniques, among others. Therefore, results of the type shown in **Fig. 12** should be used with caution and having these limitations in mind.

4. The bid amounts obtained from the Caddo County District 2 office (Fig. 4) are higher than the predicted amounts based on other projects in Fig. 12. We sought to obtain the as-built costs of these GRS bridges to determine if such difference indeed existed with as-built values. However, such information has not become available as of the date of this report.

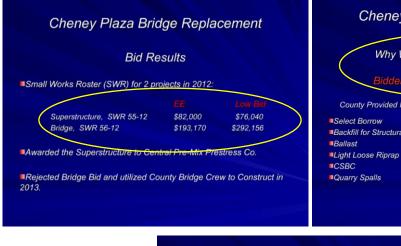

An example case study for a significantly higher contractor bid amount than the actual project cost (and the engineer's estimate) is provided in **Fig. 14** (highlighted in yellow), which also shows significant cost savings on the actual cost of a GRS-IBS (\$137/sqft deck area) relative to a typical conventional bridge (\$250/sqft deck area). Additional case-study evidence for significant cost-savings in GRS bridge projects relative to conventional abutments is shown in **Fig. 15**, which is based on the cost analysis of more than 12 GRS bridges in Pennsylvania.

18

Figure 13. Large-bock bridge abutments in Hamilton County, OH that resulted in \$40,000 cost savings (Redi-Rock 2020)

5. Another factor contributing to cost-savings in the bridge projects in Grant County and Kay County is the bundling of the projects in those counties, which would generally lead to more cost-effective projects. Other state DOTs and counties have also recognized the value of bundling their bridge construction projects and incorporating GRS abutments in replacing structurally deficient bridges. For instance, a case study by Valmont<sup>™</sup> Structures on their Con-Struct<sup>®</sup> bridge units in Midland County, MI stated that:

### Cheney Plaza Bridge Replacement

Why Was The Low (only) Bid So High ?

County Provided Material Sources for the following:

Backfill for Structural Earth Wall

No settlement, displacement of Block, or distortion in the wall alignment

No Pavement Cracking HMA exhibiting no cracking at the bridge interface

Figure 14. (top) Example high bid on a GRS-IBS, highlighting the importance of contractor training and pre-bid conference to obtain reasonable bids; also, cost comparison with a typical conventional bridge; (bottom) Reported performance of the same GRS bridge (Source: Neil Carroll, FHWA 2015)

"These bridge systems, that can be bundled and self-installed, were the answer when Midland County Road Commission and their structural consultant, OHM Advisors, were looking for an economical method to replace two structurally deficient bridges, the Orr Road bridge over Weaks Drain and the Grey Road bridge over Bullock Creek. To get the most bang for their buck, Midland County chose to combine multiple innovative cost-cutting measures:

- Bundling the bridges into a single package
- *Pre-ordering the bridge superstructures to be manufactured at the same time*
- Incorporating Geosynthetic Reinforced Soil (GRS) abutments (Fig. 16)
- Utilizing the Con-Struct Galvanized Steel Press-Brake-Formed Tub Girder Bridge System."

Figure 15. Cost comparison between GRS and conventional bridges in PA (Source: Randy Albert, FHWA 2015)

Figure 16. Example ABC on Geosynthetic Reinforced Abutments in Midland County, MI (Valmont<sup>™</sup> Structures 2021)

**Figures 17** shows cost comparisons between GRS bridges planned for construction (i.e. projected costs) in Grant County and conventional bridges in Caddo and Kay counties (data from Mr. Tom Simpson (BIA). In contrast to the results in **Fig. 7**, data in **Fig. 17** indicate that projected costs of bundled GRS bridges in Grant County are less than those of conventional bridges for the cases examined. These cost data indicate that GRS abutments could indeed be cost effective relative to comparable conventional solutions.

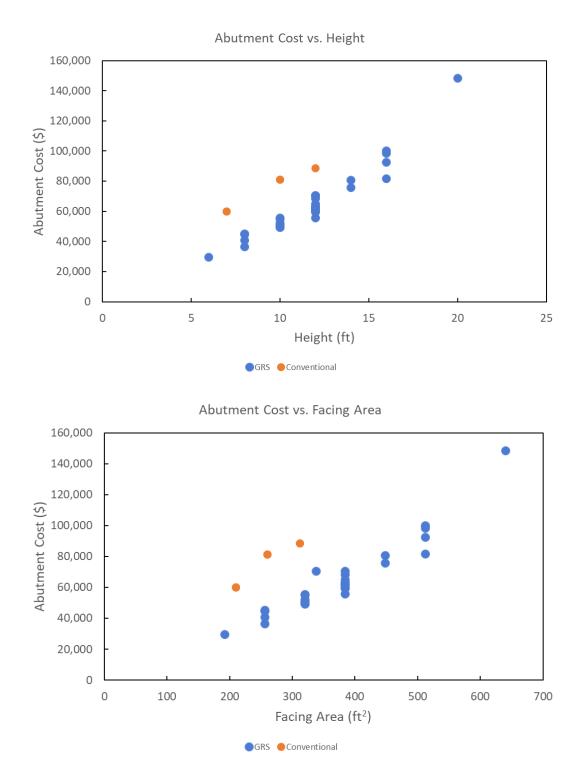

Figure 17. Comparison of abutment costs between GRS bridges in Grant County and selected conventional bridges (with available cost data) as a function of abutment height and facing area

Following a series of communications with Mr. Max Hess (Grant County Commissioner, District 1), we also received cost documents on several conventional bridges in their district, an example of which is provided in **Fig. 18**. Through subsequent communications with Mr. Hess, we were able to determine the portion of the total costs that was on the abutments only, which is highlighted in **Fig. 18** and the legend provided in the figure. Cost analysis for all conventional bridges with available data in that district is summarized in **Table 5**.

		Cost

Figure 18. Cost data on an example conventional bridge in Grant County with cost items for the superstructure and the abutments identified separately

We have also been in communication with Mr. Hess' and CED 8 offices to see if the corresponding abutment size information would also be available for direct comparison of the cost data with those on GRS bridges. However, as of the date of this report such information has not been available. Meanwhile, inspection of data in **Table 5** indicates that the conventional bridges in Grant County District 1 were very cost-effective, which is attributed to the use of experienced local force and efficient procurement of construction materials (e.g. recycled beams, etc.) on the part of the commissioner's office.

### 4. KAY COUNTY

Four (4) GRS-IBS bridges were built over Dry Creek near Blackwell in Kay County during the period April 2014-February 2015, which provided a unique opportunity for a sideby-side comparison of their cost and performance with one another and with two additional conventional bridges (i.e. a total of six bridges were constructed over the said period). The bridges are numbered as shown in **Fig. 19**, and their construction-related information is presented in **Table 6**. **Figure 20** shows before and after photographs of an example GRS bridge from this ensemble.

Figure 21 shows cost comparisons between GRS bridges in Kay County and conventional bridges in Caddo and Kay counties. Similar to the results shown in Fig. 17, data in Fig. 21 indicate that GRS abutments could indeed be cost effective relative to comparable conventional solutions.

#### 5. LINCOLN COUNTY

Project costs of the only GRS-abutment bridge constructed to date in Lincoln County (Yates Bridge over Spring Creek) are compared with those of a conventional bridge (i.e. Guilliam Bridge) that had been considered at the time, using the data provided by Mr. Tom Simpson, PE. The GRS abutment was the only alternative considered for this project. However, the bidding results of October 19, 2015 for a pile-supported abutment bridge with comparable bridge dimensions were also obtained. **Figure 22** shows selected information on the two bridges including some design specifications and bill of quantities.

**Figure 23** shows bid tables for both bridges, which include comparisons between different contractor bids and engineer's estimate. The GRS and the conventional bridges were comparable with respect to factors such as their width, abutment height, span length, ADT and superstructure. Contractors' quotes on the two projects were quite different; but after ignoring the highest unit prices, it can be observed that the unit cost of the superstructure (\$/ft<sup>2</sup>) for the conventional bridge is higher than that of the GRS-IBS bridge (i.e. \$39.03/ft<sup>2</sup> vs. \$31.27/ft<sup>2</sup>). However, this difference seems to be counterbalanced by a somewhat higher cost of the GRS abutment relative to the pile support. Even though these prices are only estimates, the data in **Fig. 23** indicate that the cost-effectiveness of GRS-IBS relative to conventional bridges could be eroded for taller abutments. In addition, since the back-slope of the GRS abutments had to be changed from 1:1 to a milder 2:1 for added stability, there were additional quantities of excavation and aggregate that were involved in order to complete the abutments. Per the estimate provided by Mr. Simpson, the actual (total) cost of the GRS bridge was approximately \$170,000, which was comparable to the engineer's estimated amount.

Figure 24 shows additional cost comparisons between the GRS bridge in Lincoln County (i.e. Yates Bridge) and smaller conventional bridges in Caddo and Kay counties, similar to those presented in Figs. 7, 17 and 21. Results in Fig. 24 provide a somewhat different perspective on the estimated cost of the conventional abutment shown in Fig. 23b, and indicate that the amount in Fig. 23b could indeed be significantly underestimated, as it does not appear to be consistent with the trend in data in Fig. 24. In contrast the abutment cost of the GRS bridge appears to be consistent with the trend in the trend in the trends observed in Fig. 24 given its abutment height.

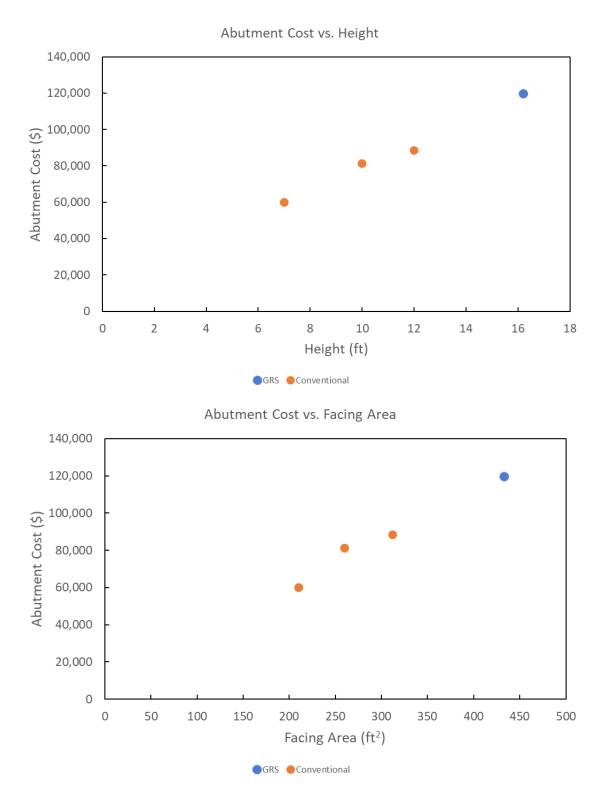

Figure 24. Comparison of abutment costs between the GRS bridge in Lincoln County and selected conventional bridges (with available cost data) as a function of abutment height and facing area

## 6. CONSTRUCTION AND TESTING OF FIELD-SCALE GRS ABUTMENTS AT THE UNIVERSITY OF OKLAHOMA

The importance of familiarity with the GRS construction process, and how it could result in cost-effective and rapid construction practice has also been demonstrated quantitatively by our research group through field-scale model construction and testing in our laboratory. **Figure 25** shows a comparison of cumulative person-hours our research group has spent to build seven (7) 8 ft-high GRS model abutments at the Fears Structural Laboratory. Six of these abutments had been constructed during a recently concluded research project sponsored by ODOT (Hatami *et al.* 2020). A seventh model using large blocks for the facing and a dense-graded fill was built during this study in the continuation of the previous project at no cost to ODOT. The construction effort in person-hours for this latest model abutment was also monitored and recorded for comparison purposes.

Abutment Models Nos.1-3, Nos. 4-6 and No. 7 were built by different teams of students with some overlapping crew members. A comparison of construction speeds for these model GRS abutments is presented in **Fig. 25**, which consistently shows that:

- Collective experience gained by each team as a result of repeat construction of the GRS abutments can increase the construction speed within each team significantly (i.e. comparing construction speeds within Models Nos. 1-3, and separately, Models Nos. 4-6).
- Maintaining any degree of continuity across construction teams even with inevitable member turnover, consistently resulted in overall reduction of construction time for each newer set of model abutments (i.e. comparing construction speeds of Models Nos. 1-3 with those of Models Nos. 4-6, and that of Model No. 7).

Implications of the above findings to field construction of GRS-IBS are discussed in the next section of this report.

### 7. SUMMARY AND CONCLUSIONS

Based on the results of this study, the following conclusions are drawn:

- Construction costs of the few GRS bridges that have been constructed in Oklahoma, have been overall either comparable to, or less than those of conventional bridges of comparable size. However, isolated cases of single GRS bridge construction that have been tried in some counties for the first time, might have posed some technical and cost-related challenges.
- 2. Construction time and costs of GRS abutment bridges are expected to decrease as more contractors become familiar with their construction techniques and QC/QA

requirements. Once these reduced construction time and costs for GRS-IBS are materialized, they will provide an even more accurate and meaningful basis for comparing their project cost and construction speed with those of conventional bridges of comparable size, which have been in construction and use for decades. For instance, Bid A in **Fig. 4** provided a more accurate sense of the GRS bridge cost relative to Bids B or C for the same project. Increased experience with GRS abutment construction throughout the state could lead to significant cost savings as a result of reduced construction time and traffic disruption, and earlier availability of the bridges and roadways for service to the users.

- 3. The cost-effectiveness of GRS abutments relative to conventional abutments could diminish significantly in the case of taller/larger abutments. For instance, the GRS bridge in Lincoln County offered a very interesting and rather unique case study due to the significant size of its abutments (i.e. over 16 ft tall). Cost estimates in Fig. 23 indicated that GRS abutments of significant size and height can become expensive and lose their otherwise typical cost advantages over conventional solutions as compared to smaller bridges (e.g. the 7-ft-tall GRS bridge abutments in Kay County). The use of large-block-facing abutments could help speed up abutment construction to some extent, leading to some cost savings in such cases. However, significant quantities of select aggregate, reinforcement material and labor necessary to build large GRS abutments could erode their otherwise, demonstrated cost advantages to some extent for very tall bridge abutments.
- 4. Factors such as familiarity of the contractors with GRS abutment construction, use of local force and materials such as recycled beams, among others, could help further reduce the cost of GRS bridges, and thereby, their widespread use in county and local projects. Therefore, an initiative to build GRS bridges by experienced contractors and through bundling of projects (such as the current projects in Grant

37

County) could serve as a cost-saving approach to replacing structurally deficient and functionally obsolete bridges across the state.

5. During the course of this study, it was observed that there is a paucity of welldocumented, cost and construction speed information on both the GRS and conventional bridges on local roads in different counties. Developing a centralized system to record and maintain such data would provide a valuable reference database for different stakeholders, which can help ensure more cost-effective bridge projects across the state in the future. This is an area that our research team can help with, and would be worth considering in the continuation of this study.
